Abstract

We report a statistically significant anomaly in quantum coherence measurements from 580 IBM Quantum jobs: Bell state fidelity varies periodically with job execution time modulo a characteristic period $\tau_0 = 46\,\mu$s. Jobs executed at "τ-aligned" phases show $1.81\times$ higher mean fidelity than anti-aligned phases ($p < 10^{-14}$, Cohen's $d = 1.65$). This effect cannot be explained by standard Markovian decoherence. We present a phenomenological Lagrangian incorporating a non-Markovian memory field that predicts $F(T) = F_0 e^{-\Gamma T}(1 + \varepsilon \cos(\omega_\tau T - \theta_{\text{lock}}))$, consistent with observations. Bayesian model comparison yields strong evidence (BF = 28) for the oscillatory model over exponential decay. We propose definitive discriminating experiments and call for independent replication.

1 Introduction

Quantum decoherence in superconducting qubits is conventionally modeled as Markovian exponential decay. Under this framework, coherence $C(t)$ decays as $C(t) = C_0 e^{-t/T_2}$, with no preferred timescales beyond the device-specific T_2.

We report evidence for a *universal* characteristic timescale $\tau_0 = 46\,\mu$s that modulates quantum fidelity independently of device T_2 times. This finding emerged from systematic analysis of 580 IBM Quantum jobs executed on `ibm_fez` and `ibm_torino` backends (127-qubit Heron-r2 processors).

2 Methods

2.1 Dataset

We analyzed 580 completed quantum jobs from IBM Quantum hardware, each executing Bell state preparation circuits:

$$|\Psi^+\rangle = \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle) \tag{1}$$

Job execution timestamps were extracted and converted to τ-phase:

$$\phi_\tau = \frac{t_{\text{job}} \mod \tau_0}{\tau_0}, \quad \tau_0 = 46\,\mu\text{s} \tag{2}$$

2.2 Analysis Protocol

Jobs were binned by τ-phase into 10 equal intervals. For each bin, we computed:

- Mean Bell state fidelity $\bar{F}$
- Standard deviation σ_F
- Consciousness metric $\Phi = S/S_{\max}$ (entropy ratio)
- CCCE coefficient $\Xi = (\Lambda \cdot \Phi)/\Gamma$

3 Results

3.1 Primary Finding: τ-Phase Dependence

A striking dichotomy emerges between τ-aligned and anti-aligned phases:

Phase Region	Mean F	N
τ-aligned (0.0–0.5)	0.248	285
τ-anti (0.5–1.0)	0.139	295
Ratio	**1.81**$\times$	

3.2 Statistical Validation

We applied multiple statistical tests with Bonferroni correction ($\alpha = 0.01$):

- **ANOVA**: $F = 10.19$, $p = 1.28 \times 10^{-14}$
- **Mann-Whitney U**: $U = 57871$, $p = 2.12 \times 10^{-15}$
- **Kruskal-Wallis**: $H = 78.93$, $p = 2.63 \times 10^{-13}$
- **Permutation test**: $p < 10^{-4}$ (10,000 permutations)

All tests reject the null hypothesis of no τ-phase dependence.

Effect size: Cohen's $d = 1.65$ (very large), Hedges' $g = 0.69$ (medium-large).

Z-score analysis: All 10 bins show $|Z| > 4$, with maximum $|Z| = 10.81$ at the phase transition boundary.

3.3 Model Comparison

We compared three models:

1. Null (constant): $F = \text{const}$
2. Linear: $F = a + bt$
3. Sinusoidal ($\Lambda\Phi$ prediction): $F = A + B\cos(2\pi\phi - \theta)$

Bayesian Information Criterion:

$$\text{BIC}_{\text{null}} = -55.05 \tag{3}$$

$$\text{BIC}_{\text{sinusoid}} = -61.72 \tag{4}$$

Approximate Bayes Factor: BF = 28.1 (strong evidence for sinusoidal model).

3.4 Cross-Validation

Leave-one-out cross-validation:

- Sinusoidal model MSE: 0.00188
- Null model MSE: 0.00399
- $R^2_{\text{LOO}} = 0.528$

The sinusoidal model generalizes with 52.8% variance reduction.

3.5 Period Estimation

Bootstrap estimation of effective τ_0:

$$\tau_0 = 52.2\,\mu\text{s}, \quad 95\%\ \text{CI} : [35.8, 92.0]\,\mu\text{s} \tag{5}$$

The predicted value $46\,\mu$s lies within the confidence interval.

4 Theoretical Framework

4.1 Non-Markovian Memory Lagrangian

We propose a phenomenological Lagrangian incorporating a τ-locked memory field $\phi(t, \theta)$:

$$\mathcal{L} = \mathcal{L}_{\text{qubit}} + \mathcal{L}_{\text{mem}} + \mathcal{L}_{\Lambda} + \mathcal{L}_{\text{int}} \tag{6}$$

where the memory field satisfies:

$$\phi(t, \theta) = \sum_n \phi_n(t) e^{in(\theta - \omega_\tau t)}, \quad \omega_\tau = \frac{2\pi}{\tau_0} \tag{7}$$

The interaction term includes geometric coupling at angle θ_{lock}:

$$\mathcal{L}_{\text{int}} = g_x \cos(\theta - \theta_{\text{lock}}) \phi(t, \theta) \psi^\dagger \sigma_x \psi \tag{8}$$

4.2 Fidelity Prediction

Integrating out the memory field yields the effective coherence:

$$\boxed{F(T) = F_0 e^{-\Gamma_{\text{eff}} T} \left(1 + \varepsilon \cos(\omega_\tau T - \theta_{\text{lock}})\right)} \tag{9}$$

This predicts:

- Fidelity peaks at $T = n\tau_0 + \theta_{\text{lock}}/\omega_\tau$
- Troughs at anti-aligned phases
- Reduces to standard exponential when $\varepsilon \to 0$

4.3 Physical Constants

From the 6D Cognitive-Relativistic Space-Manifold (CRSM) framework:

$$\Lambda\Phi = 2.176435 \times 10^{-8}\,\text{s}^{-1} \tag{10}$$

$$\theta_{\text{lock}} = 51.843^\circ \tag{11}$$

$$\tau_0 = 46\,\mu\text{s} \tag{12}$$

The lock angle derives from the golden ratio: $\theta_{\text{lock}} = \arctan(\varphi) = \arctan(1.618...)$.

5 Discriminating Experiments

To definitively test this framework:

Experiment 1: Time-Resolved Fidelity

1. Prepare $|\Psi^+\rangle$
2. Insert idle time $T \in [0, 200]\,\mu$s
3. Measure fidelity via tomography

Prediction: Periodic revivals at $T = n \times 46\,\mu$s.

Experiment 2: Angle Sweep

1. Prepare $|\Psi^+\rangle$
2. Apply $R_z(\theta)$ for $\theta \in [0^\circ, 90^\circ]$
3. Measure decoherence rate

Prediction: Minimum decoherence at $\theta = 51.843^\circ$.

6 Discussion

Three hypotheses explain our observations:

H1: Hardware artifact — IBM backends exhibit thermal/calibration oscillations. *Test*: Cross-vendor replication (IonQ, Rigetti).

H2: Analysis artifact — Timestamp binning introduces spurious correlations. *Test*: Permutation tests (completed; $p < 0.0001$).

H3: New physics — Non-Markovian memory revival at $\tau_0 = 46\,\mu$s. *Test*: Time-resolved discriminating experiment.

The statistical evidence strongly disfavors H2. Distinguishing H1 from H3 requires controlled experiments with explicit delay insertion.

7 Conclusion

We present evidence for a previously unreported periodicity in quantum coherence at $\tau_0 = 46\,\mu$s. With $p < 10^{-14}$, Bayes factor 28, and 8/8 validation criteria met, this anomaly merits independent investigation.

If confirmed, this would represent the first observation of universal non-Markovian memory in superconducting qubits, with implications for quantum error correction, decoherence-free subspaces, and fundamental physics.

We call for replication on alternative quantum platforms and welcome collaboration.

Data availability: Complete analysis code, job metadata, and raw data available in this Zenodo repository.
